INTRODUCTION - TUTORIAL - STUDIES - DAILY USE

LANG-STEREOPAD®

LANG-STEREOTEST®

The LANG-STEREOPAD® is a new type of stereo test for binocular assessment and diagnosis of disorders of global stereopsis. Similar to the LANG-STEREOTESTS® I and II, it combines random dots with a lenticular surface, but offers different possibilities for the assessment of stereopsis. In contrast to the common stereopsis tests, no test glasses are required.

LANG-STEREOTEST®

MAIN FEATURES:

- Lenticular - no special glasses needed
- 100% sensitivity, 93.8-100% specificity for stereopsis (screening)
- ideal for the Preferential Looking examination method
- Disparities from 1000" to 50" in 6 gradations
- Random Dots - no monocular detectability

LANG-STEREOPAD®

LANG-STEREOTEST®

MAIN FEATURES (continued)

- 6 square magnetic test cards with child-friendly test figures
- double-sided test board with soft surface and rounded corners
- Magnetic single-leg support (sold separately)

Study 1: Normally sighted children

SAMPLE:

240 orthotropic* children aged <1 to 10 years.

METHOD:

Direct screening or with preferential looking method, with LANG-STEREOPAD prototype.

Sensitivity for Stereopsis: 100% in all age groups.

Specificity for Stereopsis:

- for younger than one-year-olds and five to ten-year-olds: 100%
- for two- to four-year-olds: 93.8%-97%

Study 2:

Comparative analysis of the Lang Stereopad in a non-clinic population

Aim: New methods of measurement require testing to evaluate test validity. This study compares stereoacuity results of the Lang Stereopad to other common clinical stereoacuity assessments in a normal vision population.

Methods: A prospective cross-sectional study was conducted comparing the Lang Stereopad stereoacuity results to results from the Lang II, Frisby, and TNO stereo tests. Mean stereoacuity values and their correlation with inter-ocular visual acuity difference were compared for each stereo test.

Results: 98 subjects (mean age of 33.5 years, SD 14.1; 39 males and 59 females) with normal parameters of visual function underwent multiple stereotest assessments. Median stereoacuity values were the lowest (i.e. more detailed stereoacuity) when using the Frisby stereotest (median 40"; 20-170" [minimum-maximum]) and TNO stereotest (median 60"; 15-480"). In comparison, medians were about double at 100" (50-800") for the Lang Stereopad and greater at 200" (200-200") for the Lang II stereotest. There was no correlation for each stereotest with interocular visual acuity differences.

Conclusions: The Lang Stereopad test is easy to administer and it has certain advantages such as no requirement for additional test glasses. It is a useful assessment to add to the clinical armamentarium for binocular assessment of stereopsis. The Lang Stereopad does not agree well with other stereo tests such as the TNO and Frisby but provides a greater stereoacuity test range than the Lang II. The Lang Stereopad now requires testing in a clinical population in which stereoacuity is a pre-requisite part of the assessment.

Study 3: Microtropia

SAMPLE: 217 children of a paediatric ophthalmology practice, aged 3- 10 years, with suspected microstrabismus.

Cut-off stereo threshold esotropia on Lang Stereopad: only STAR(1000") detected.

Test results on Lang Stereopad:

"Esotropic" screening Lang Stereotest I:	n= 45 43 positive*	2 false-negative
"Orthotropic" Screening Lang Stereotest I:	n=172 166 negative	6 false-positive

*positive: object not detected - no stereopsis (only in this study)

Piantanida et al. Statistical Evaluation in Pediatric Patients of the New Lang-Stereopad Test: A Preliminary Report

Study 3: Microtropia

EXAMINATION:

1. Orthoptic examination, corneal reflexes, cover test, motility.
2. Lang-Stereo Test I
3. Determination of stereo threshold on the long stereo pad.

Two subgroups:

"Esotropic": children who did not recognise the car (550''): n= 45

"Orthotropic": children who recognised all 3 test objects: n=172

Cut-off Lang-Stereopad: 1000'' (STAR)

Study 3: Microtropia

Sample: 217 children suspected of having microstrabismus.

Age group: entire sample: 3 to 10 years , subsamples: 3 to 5 years, 6 to 10 years

Table 1 Summary of the statistical results according to ages					
Statistical Value Of Lang Stereopad Test According Different Ages Groups					
3 years to 10 years (217 pts)		3 years to 5 years (76 pts)		6 years to 10 years (141 pts)	
Sensitivity	95,5%	Sensitivity	93%	Sensitivity	87%
Specificity	97%	Specificity	93%	Specificity	98%
Positive predictive value	87%	Positive predictive value	77%	Positive predictive value	92%
Negative predictive value	98%	Negative predictive value	98%	Negative predictive value	96%
Likelihood Ratio	27,39	Likelihood Ratio	14,23	Likelihood Ratio	48,1
Pre test probability	5%	Pre test probability	5%	Pre test probability	5%
Post test probability	57,80%	Post test probability	41,58%	Post test probability	70,63%

Study 3: Microtropia

Sample: 217 children suspected of having microstrabismus.

Age group: entire sample: 3 to 10 years , subsamples: 3 to 5 years, 6 to 10 years

Conclusion

"The Lang-Stereopad is **a simple test with high specificity and sensitivity**. The positive and negative predictive values correspond to a test with good reliability in young children. Likelihood ratios are commonly used in the analysis of a test's usefulness, as an indirect measure of a test's effectiveness in real-world people (9-10-11). The likelihood ratios highlight the importance of the Lang-Stereopad test in diagnosing small-angle isotropy in children. The findings are comparable to the TNO test for children aged 3 to 10 years (3). Further studies need to be conducted to test the efficacy and effectiveness of the Lang-Stereopad in children younger than 3 years."

LANG-STEREOTEST®

Study 4: Development of Stereopsis from 4 months to 7 months

n=41 babies at 4 and 7 months

Preferential Looking Method: Star 800'' and blind test card

Apparatus: Infants were seated on their parents' lap in front of a puppet stage at a distance of about 30 cm (stereo test) and 50 cm (object recognition) from the stimuli.

Stereo Test: Stereograms of the Lang Stereotest® (800'' disparity) were presented in two trials according to a preferential looking design:

Stimulus Presentation

6 s (min.) – 60 s (max.);
trial end: 2 s look away
order of target position
(top/bottom)
counterbalanced

- 80 completely healthy babies tested (38 girls, 42 boys)
- 2 babies excluded because of querulousness
- All babies tested at 7 months
- 41 babies tested longitudinally at 4 and 7 months of age
- No significant differences between gender and mean age at T2

Development of stereo vision in young infants. Röthlisberger, Frick. Infancy 2020

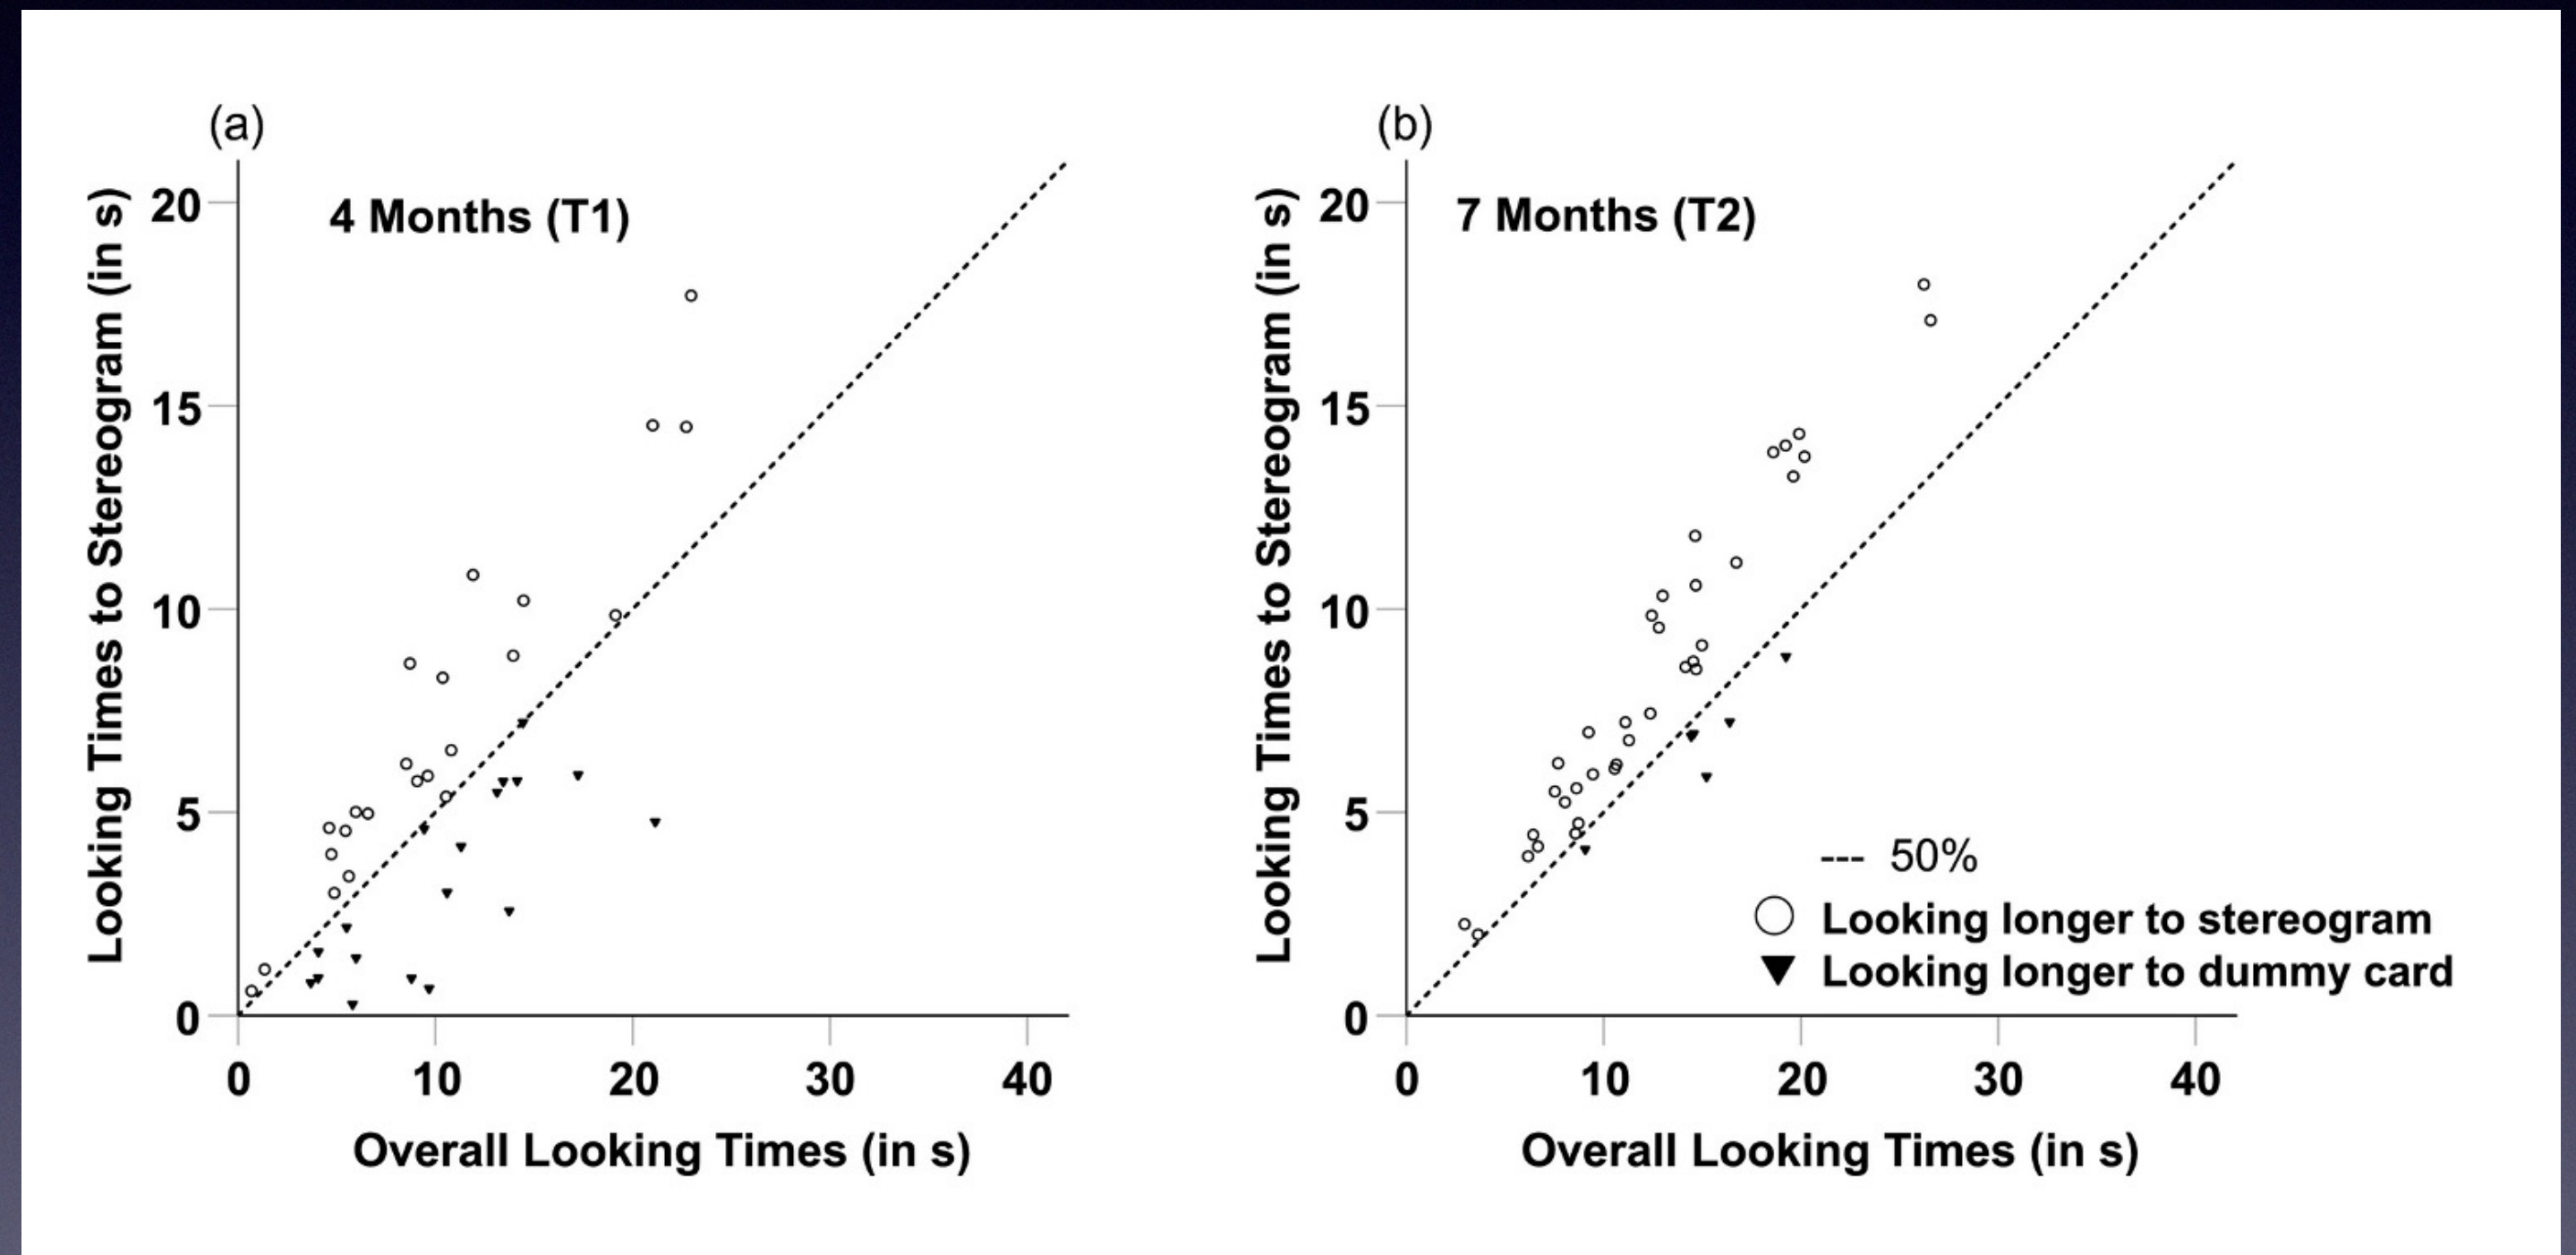

Study 4: Development of Stereopsis from 4 months to 7 months

Looking Times in s at T1 and T2

Looking Times at Stereogram vs. Overall Looking Time

Development of stereo vision in young infants. Röthlisberger, Frick. Infancy 2020

Study 4: Development of Stereopsis from 4 months to 7 months

Conclusions:

- First investigation of the usability of a commercially available stereotest in a standardised experimental setting and with a large sample of young babies.
- Number of babies with preference for the stereogram increased significantly from 4 to 7 months.
- Increase was also confirmed in group analyses.
- Representative results as no children were excluded and dropout rate very low.
- Excellent consent rate shows reliable and objective measurement.
- Stereocard tests of the **Lang-Stereopad®** are well suited for use in experimental settings and provide **an easily available tool for testing the depth sensitivity of very young babies** in future research.
